

---

When a person has a heart attack, they often have chest pain and discomfort which can lead to fainting. There are many things that can be done to make sure this doesn't happen. One is the use of an automatic external defibrillator (AED). They may be portable or mounted on furniture as needed. The AED will analyze the heart rhythm and determine if shocks are necessary along with other important information such as how many pulses per minute there should be and what types of shocks will work best for them. This device also comes with a loudspeaker that gives out instructions in different languages to those who would need it including those who don't speak their native language fluently. A defibrillator does not make a heart attack go away, but it can keep more damage from occurring. It is used first on a person with a heart attack until the medical professional arrives. They may also use another device called an automated external defibrillator (AED) to provide emergency treatment instead of working on someone that is having a heart attack or similar condition. These defibrillators come in portable and wall mounted versions. The portable ones can be taken anywhere, but the wall mounted ones must be installed where they will be used most often, such as at work or in public places. The AED will analyze the heart rhythm and determine if shocks are necessary along with other important information such as how many pulses per minute there should be and what types of shocks will work best for them. This device also comes with a loudspeaker that gives out instructions in different languages to those who would need it including those who don't speak their native language fluently. After an AED is used on someone with a heart attack, they are taken to the hospital where they will most likely have surgery if their heart is already in serious condition. If their heart is in less serious condition, they may require further treatment in the hospital or in the home if they are likely to need it. When a person has a heart attack, they often have chest pain and discomfort which can lead to fainting. There are many things that can be done to make sure this doesn't happen.
